#### Abstract

N-Acetylmethanopyrrolidine methyl ester and its four 5-syn/anti-fluoro and hydroxy derivatives have been synthesized from 2-azabicyclo[2.2.0] hex-5-ene, a 1,2-dihydropyridine photoproduct. These conformationally constrained mimics of idealized $\mathrm{C}^{\beta}$ gauche and $C^{\beta}$-anti conformers of pyrrolidines were prepared in order to determine the inherent bridge bias and subsequent hetero-  atom substituent effects upon trans/cis amide preferences. The bridgehead position and also the presence of gauche(syn)/anti-5fluoro or 5 -hydroxy substituents have minimal influence upon the $K_{\mathrm{T} / \mathrm{C}}$ values of $N$-acetylamide conformers in both $\mathrm{CDCl}_{3}$ $(43-54 \%$ trans $)$ and $\mathrm{D}_{2} \mathrm{O}(53-58 \%$ trans $)$. O-Benzoylation enhances the trans amide preferences in $\mathrm{CDCl}_{3}(65 \%$ for a syn-OBz, $61 \%$ for an anti-OBz) but has minimal effect in $\mathrm{D}_{2} \mathrm{O}$. The synthetic methods developed for $N$-BOC-methanopyrrolidines should prove useful in the synthesis of more complex derivatives containing $\alpha$-ester substituents. The $K_{\mathrm{T} / \mathrm{C}}$ results obtained in this study establish baseline amide preferences that will enable determination of contributions of $\alpha$-ester substituents to trans-amide preferences in methanoprolines.

## ■ INTRODUCTION

The ability of amides to exist as cis-trans isomers has important implications for protein structure and function. ${ }^{1}$ The particular behavior of amides derived from the secondary amine proline has engendered much interest in this regard because of the importance of proline cis-trans isomerization to biological functions ${ }^{2}$ and structure of proteins. ${ }^{3}$ There is an emerging interest in bioengineering applications of proline and substituted prolines. ${ }^{4-6}$

$N$-Acetylproline methyl ester (Pro) $\mathbf{1}$ not only is present as a mixture of cis-trans isomers but also exists in a variety of ring conformations. Two of these in which $\mathrm{C}^{\gamma}$ experiences a large out-of-plane displacement are major, ${ }^{7}$ and we refer to them as $\mathrm{C}^{\gamma}$-endo
( $\mathrm{C}^{\gamma}$-pucker toward the ester) and $\mathrm{C}^{\gamma}$-exo ( $\mathrm{C}^{\gamma}$-pucker away from the ester). Substituents at $\mathrm{C}^{\gamma}$, as in $(2 S, 4 S)$-4-fluoroproline (flp) 2 and ( $2 S, 4 S$ )-4-hydroxyproline (hyp) 3 , affect the direction of ring pucker and also influence amide cis/trans conformational preferences. ${ }^{3}$ The two effects appear to be correlated. ${ }^{3 a, 4,8}$ In an effort to control the ring pucker variable and isolate the remaining effect of a substituent upon amide cis-trans preferences, we synthesized the 2 -azabicyclo[2.1.1]hexanes 4-6 (Table 1), ${ }^{9}$ analogues of Pro 1, flp 2, and hyp 6. N-Acetylmethanoproline methyl ester (MetPro) 4 displays a Pro 1 residue with both idealized $\mathrm{C}^{\gamma}$ exo and $\mathrm{C}^{\gamma}$-endo ring puckers. The substituted 4-anti-fluoromethanoproline (Metflp) 5 and 4-anti-hydroxymethanoproline (Methyp) 6, when viewed from the perspective of the substituentbearing bridges, are pyrrolidines (bolded bonds) with constrained $\mathrm{C}^{\gamma}$-exo ring puckers. The relative substituent effects on $K_{T / C}$ for these methanoprolines $4-6$ was essentially invariant in $\mathrm{D}_{2} \mathrm{O}$, although in the less polar aprotic solvents $\mathrm{CDCl}_{3}$ and 1,4-dioxane$d_{8}$ Metflp 5 had a slightly larger trans preference than the others.

${ }^{a}$ Values of $K_{\mathrm{T} / \mathrm{C}}$ were measured at $25{ }^{\circ} \mathrm{C}$ using ${ }^{19} \mathrm{~F}$ NMR spectra for fluoro isomers and ${ }^{13} \mathrm{C}$ NMR for MetPro 4 and Methyp 6 (see ref 9). ${ }^{b}$ Values in ref 9 were measured in $\mathrm{D}_{2} \mathrm{O} / \mathrm{CD}_{3} \mathrm{OD} \sim 4: 1$.

This result was taken to indicate that the $\gamma$-substituent effect is primarily related to ring pucker and a resultant enhancement of the interaction between the amide carbonyl oxygen and ester carbonyl carbon.

Our previous study ${ }^{9}$ did not identify unresolved issues associated with using methanoprolines $4-6$ as mimics of prolines $\mathbf{1 - 3}$. For example, it is not known if the carbonyl group of the amides in the mimics $4-6$ has a structurally-related preference to be adjacent to the bridgehead $\mathrm{H}_{1}$ or the methylene $\mathrm{H}_{3}$ position. Knowledge of the amide preference of a methanopyrrolidine (Metpyr) 7 that is missing the $\alpha$-ester adjacent to nitrogen (Figure 1) is necessary in order to determine the effect of a 3-ester substituent upon amide conformations.

Additionally, the scope of the methanoproline substituent effect study was limited to the Metflp 5 and Methyp 6 stereoisomers related to flp 2 and hyp 3 by the synthetic approach available at that time. Thus, we were unable to address the generality of the finding for other methanoproline stereoisomers related to $(2 S, 4 R)$-4-fluoroproline $8(\mathrm{Flp})$ and the biologically relevant ( $2 S, 4 R$ )-4-hydroxyproline (Hyp) 9 as to whether $K_{\mathrm{T} / \mathrm{C}}$ values are always independent of substituent and depend mainly on ring pucker. To answer these questions, a different synthetic approach is needed to prepare methanofluoroprolines (MetFlps) 14 and 15, whose idealized $\mathrm{C}^{\gamma}$ ring puckers contain either exo(gauche)- or endo(anti)-Flp 8 conformers, embedded in

bold for emphasis in Scheme 1. The same is true for methanohydroxyprolines (MetHyps) 16 and 17, related to Hyp 9. A possible synthetic approach to methanoprolines could utilize as key synthons the methanopyrrolidines $10 \mathrm{a}-13 \mathrm{a}$ or related O -protected derivatives.

Herein, we describe 1,2-dihydropyridine-based syntheses of Metpyr 7 as well as $N$-acetyl- 5 -syn- and 5 -anti-F(OH)-substituted methanopyrrolidines 10b-13b. The configurational preferences determined for these amides reveal that only small inherent trans/cis amide biases accompany the use of methanoprolines as idealized $\mathrm{C}^{\gamma}$-puckered proline mimics. In a separate paper, we shall show how $N$-Boc-methanopyrrolidines 10a-13a, or related O-silylated derivatives, can serve as key synthons for a directed lithiation approach to the desired methanoproline derivatives $14-17 .^{10,11}$

## ■ RESULTS AND DISCUSSION

Metpyr 7 was prepared in $70 \%$ yield from $N$-Boc-methanopyrrolidine ${ }^{10}$ by removal of the Boc group with trifluoroacetic acid followed by acetylation with acetyl chloride.

Synthesis of 5-Fluoromethanopyrrolidines. N-Boc-5-syn-fluoro-Metpyr 10a was synthesized, as shown in Scheme 2, from pyridine-derived intermediate 18 that was prepared by a secondchance rearrangement route. ${ }^{12}$ Conversion of fluoro alcohol 18 to the thionocarbonate 19 using $O$-phenyl chlorothionoformate ${ }^{13}$ followed by reductive deoxygenation afforded the N -benzyloxycarbonyl fluoride 20. Reductive removal of the protecting group using $\mathrm{H}_{2} / \mathrm{Pd}(\mathrm{OH})_{2}$ in methanol in the presence of $(\mathrm{BOC})_{2} \mathrm{O}$ afforded the $N$-BOC-5-syn-fluoro synthon 10a. The reduction of 20 in methanol followed by addition of acetyl chloride afforded the N -acetyl-5-syn-fluoroamide 10b.

In the 5 -anti-fluoro series, N -Boc-5-anti-fluoro-methanopyrrolidine 11a was synthesized from 1,2-dihydropyridine photoproduct 21 as shown in Scheme 3. ${ }^{14,15}$ Addition of BrF to 11a was accompanied by rearrangement to afford the 5-anti-bromo-

6-anti-fluoro azabicycle 22. Characteristic for the rearranged 2azabicyclo[2.1.1] hexane structure for 22 was the ${ }^{1} \mathrm{H}$ NMR W-plan coupling between the bridgehead proton $\mathrm{H}_{1}$ at $\delta 4.61$ with $\mathrm{H}_{4}$ at $\delta$ $3.20\left(J_{1,4}=7.2 \mathrm{~Hz}\right)$. Similarly, the 5-anti-6-anti stereochemistry for 22 was demonstrated by its W-plan coupling of proton $\mathrm{H}_{5}$ at $\delta$ 4.18 with $\mathrm{H}_{6}$ at $\delta 5.07\left(J_{5,6}=7.5 \mathrm{~Hz}\right)$, as well as their vanishingly small couplings to the flanking bridgehead protons $\mathrm{H}_{1}$ and $\mathrm{H}_{4} .{ }^{12,14}$ Bromo fluoride 22 was reductively debrominated to give 5-antifluoride 23. Reductive removal and reprotection, as described above for fluoride 20, afforded either the N -BOC-5-anti-fluoro synthon 11a ${ }^{16}$ or the $N$-acetyl fluoride 11b.

Synthesis of 5-Hydroxymethanopyrrolidines. For the 5 -syn-hydroxy series, a silylated derivative of alcohol 12a, $N$-Boc-5-syn-OTBS-methanopyrrolidine 28, was synthesized from iodohydrin 24 as shown in Scheme $4 .^{12,14}$ An inefficient, but necessary, mercuric bromide-mediated nucleophilic substitution reaction, during which nitrogen has migrated from $\mathrm{C}_{1}$ to $\mathrm{C}_{6}$, afforded the bromohydrin 25 . The rearranged 2 -azabicyclo[2.1.1] hexane structure of 25 was confirmed by the characteristic ${ }^{1} \mathrm{H}$ NMR W-plan coupling between bridgehead proton $\mathrm{H}_{1}$ at $\delta 4.44$ with $\mathrm{H}_{4}$ at $\delta 2.92\left(J_{1,4}=6.8 \mathrm{~Hz}\right)$ and a geminal $\mathrm{H}_{3}$ proton at $\delta 3.41\left(\mathrm{~d}, J_{3,3^{\prime}}=11.3 \mathrm{~Hz}\right)$ that is not further coupled to $\mathrm{H}_{4}$. The singlet at $\delta 3.57$ identifies $\mathrm{H}_{5}$ as syn, since there is no coupling with $\mathrm{H}_{1}$ or $\mathrm{H}_{4}$. Also, the absence of W-plan coupling between $\mathrm{H}_{5}$ and $\mathrm{H}_{6}$ at $\delta 4.77$ identifies $\mathrm{H}_{6}$ as anti. With the crucial 5-synalcohol in place, protection of the alcohol as the TBS ether 26

followed by reductive debromination gave the ether 27. Hydrogenolysis in the presence of $(\mathrm{BOC})_{2} \mathrm{O}$ gave N -BOC-5-syn-OTBS synthon 28.
$N$-Acetyl-5-syn-O-benzoate 29 and $N$-acetyl-5-syn-alcohol 12a were prepared from 25 as shown in Scheme 5. Benzoylation of alcohol 25 gave a benzoate 29 that was reductively debrominated to afford benzoate 30. Hydrogenolysis and acetylation afforded the amide ester 31, which upon methanolysis afforded 5-synalcohol 12b.

For the 5-anti-hydroxy series, N-BOC-5-anti-alcohol 13a was prepared from bromoacetate 32, ${ }^{17}$ as shown in Scheme 6. Reductive debromination gave acetate 33. Methanolysis to 34 and then hydrogenolysis in the presence of $(\mathrm{BOC})_{2} \mathrm{O}$ gave $N$-BOC alcohol 13a. For investigation of trans/cis amide preferences, alcohol 13a was converted to the $N$-acyl benzoate ${ }^{18} 36$, and this was converted by methanolysis to the alcohol $\mathbf{1 3 b}$.

NMR Analysis of $K_{\mathrm{T} / \mathrm{C}}$ for Substituted Methanopyrrolidines. A planar amide carbonyl in methanopyrrolidine 7 might be eclipsed with $\mathrm{H}_{1}$ in a cis conformation or staggered between the two $\mathrm{H}_{3}$ methylene protons in a trans orientation (Figure 2). Further, substituents might alter whatever inherent stereochemical preference might exist for 7. To resolve these issues, and to establish baseline amide conformational preferences for conformationally constrained methanoprolines with heteroatom substituents, we determined $K_{T / C}$ for the 5-syn- and 5-anti-fluoro-, hydroxy-, and benzoyloxymethanopyrrolidines in Figure 2.

Amide trans/cis ratios shown in Table 2 were obtained by integration of nonoverlapping ${ }^{1} \mathrm{H}$ or ${ }^{19} \mathrm{~F}$ NMR peaks. The percentages of trans isomers obtained by separate ${ }^{1} \mathrm{H}$ NMR integrations are reliable $\pm 1 \%$. For an individual structure, isomer ratios can depend on the protons chosen to be integrated and compared and the percentage of trans isomer can vary from the average by $\pm$ $1.5 \% .{ }^{19} \mathrm{~F}$ and ${ }^{1} \mathrm{H}$ ratios ( $K_{\mathrm{T} / \mathrm{C}}$ ) differ by no more than 0.1 .

There is only a slight solvent dependence for methanopyrrolidine amide preferences of 7 and $\mathbf{1 0 b} \mathbf{- 1 3 b}$ (entries $1-5$ Table 2). In polar protic $\mathrm{D}_{2} \mathrm{O}$, the $54 \%$ trans amide preference shown by MetPyr 7 is relatively unchanged ( $\pm 1 \%$ ) by either the syn or anti, fluoro or hydroxy, heteroatom substituents of 10b-13b. In $\mathrm{CDCl}_{3}$ solvent there is a bit more sensitivity to solvent ( $43-54 \%$ trans). The $5-$ syn-F 10b and 5 -anti-F isomers $\mathbf{1 1 b}$ (entries 2 and 3) show essentially the same trans preferences in $\mathrm{CDCl}_{3}$ within a few percent as the parent substrate 9 (entry 1 ), indicating that the dipolar $\mathrm{C}-\mathrm{F}$ bond does not have a significant effect on amide preference for these methanopyrrolidine derivatives. With alcohol substitution, the 5 -syn-OH 12b (entry 4) in $\mathrm{CDCl}_{3}$ has a clear cis amide preference, while the 5 -anti-OH 15b (entry 5) has little amide preference.

The $K_{\mathrm{T} / \mathrm{C}}$ results in Table 2 in apolar $\mathrm{CDCl}_{3}$ solvent are in somewhat qualitative agreement with gas-phase relative energy calculations that generally favor small trans amide preferences. Only the 5 -syn-OH 12b, in agreement with experiment, is calculated to have a cis amide preference. An X-ray analysis of $\mathbf{1 2 b}$ shows that that there is no unusual distortion of the ring or internal hydrogen bonding interaction in the solid phase; the

Figure 2. Amide conformations for methanopyrrolidines.
amide nitrogen is nearly flat in both the cis and trans amide forms (see the Supporting Information).

Benzoylation of the alcohol groups results in little change in preference for trans amides in $\mathrm{D}_{2} \mathrm{O}$ for both the $5-s y n-\mathrm{OBz} 31$ (entry 6) and 5-anti-OBz 36 (entry 7) isomers. However, upon benzoylation the trans preference is enhanced in the less polar aprotic solvent $\mathrm{CDCl}_{3}$. Especially noteworthy is the switch from a cis amide preference for 5-syn-OH 12b (entry 4) to a clear trans amide preference for the $5-5 y n-\mathrm{OBz} 31$. In this constrained ring system a change in preferred ring pucker upon $O$-acylation can be ruled out as the cause of the enhancement effect. ${ }^{5 \mathrm{~b}, \mathrm{f}}$

## CONCLUSION

$N$-Acetylmethanopyrrolidine and its 5-syn/5-anti-F(OH) derivatives have been synthesized from pyridine via a 1,2-dihydropyridine photoproduct. The trans/cis amide preferences ( $K_{\mathrm{T} / \mathrm{C}}$ ) for the parent 7 were compared with those of the stereoisomeric pairs of $5-\operatorname{syn}($ gauche $) /$ anti-fluoro $10 \mathbf{b} / \mathbf{1 1 b}$, hydroxy $\mathbf{1 2 b} / \mathbf{1 3 b}$, and $\mathrm{O}-\mathrm{Bz}$ isomers $31 / 36$ in both $\mathrm{D}_{2} \mathrm{O}$ and $\mathrm{CDCl}_{3}$ solvent. The substituent effect differences ( $K_{\mathrm{T} / \mathrm{C}}$ functionalized isomer $-K_{\mathrm{T} / \mathrm{C}}$ for 7) were extremely small $\left(\Delta K_{\mathrm{T} / \mathrm{C}}=-0.3\right.$ to +0.1$)$ for all cases studied, with the single minor exception of the OBz isomers in $\mathrm{CDCl}_{3}\left(\Delta K_{\mathrm{T} / \mathrm{C}}=0.5-0.7\right)$. Further, in all of the pairs of stereoisomers studied the trans/cis amide preference was minimally influenced by the stereochemical orientation of the substituent ( $K_{\mathrm{T} / \mathrm{C}}$ syn-isomer $-K_{\mathrm{T} / \mathrm{C}}$ anti-isomer $=\Delta K_{\mathrm{T} / \mathrm{C}}=-0.2$ to +0.3 ).

The small trans amide preferences for methanopyrrolidine 7 in $\mathrm{CDCl}_{3}$ or $\mathrm{D}_{2} \mathrm{O}$ show that it is the interaction of the $\alpha$-ester group and the amide of MetPro 4 that plays a major role in determining trans/cis ratios. Further, the small trans amide preferences for the substituted fluoro- and hydroxy-methanopyrrolidines is confirmation of previous work with the stereoisomers Metflp 5 and Methyp 6 that indicated the remote anti heteroatom has little additional effect upon trans amide preferences. ${ }^{9}$ The findings with rigid methanopyrrolidines are consistent with the proposal for prolines that substituent influences upon the pucker energetics of ring conformations, and the resulting impact upon the amide carbonyl and proline side-chain

carbonyl interaction, play the major role in determining trans/cis amide equilibria. ${ }^{3 \mathrm{a}, 4,8}$

For the four possible N -acetyl-5-fluoro- and -5-hydroxymethanopyrrolidines, we now have obtained $K_{T / C}$ values that establish baseline amide preferences in the absence of $\alpha$-ester functionality. With this evidence, it will be possible to determine the contribution to trans amide preferences by $\alpha$-ester substituents when other methanoprolines are synthesized. The $N$-BOCmethanopyrrolidines $\mathbf{1 0 b}, \mathbf{1 1 b}, \mathbf{2 8}$, and $\mathbf{1 3 b}$ should prove useful in this endeavor to prepare fluoro- and hydroxymethanoprolines 14-17, constrained mimics of Flp and Hyp in idealized $\mathrm{C}^{\gamma}$-exo and $\mathrm{C}^{\gamma}$-endo conformations through which insights may be gained concerning amide preferences of prolines.

## ■ EXPERIMENTAL SECTION

General Methods. Thin-layer chromatography was performed on precoated plates of silica gel GF $250 \mu \mathrm{~m}$. Column chromatography was performed on silica gel, Merck grade 60 (230-400 mesh). Reagent chemicals were obtained from commercial suppliers, and reagent grade solvents were used without further purification. The standard for ${ }^{1} \mathrm{H}$ NMR was $\mathrm{CHCl}_{3} \delta 7.26$, for ${ }^{13} \mathrm{C}$ NMR $\mathrm{CDCl}_{3} \delta 77.0$, and for ${ }^{19} \mathrm{~F}$ NMR $\mathrm{CFCl}_{3} \delta 0.00$; undecoupled ${ }^{19} \mathrm{~F}$ spectra were referenced indirectly against a D-lock and required minor shift correction. Some NMR resonances appear as pairs because of carbamate conformations and italics denote minor rotamer peaks. Assignments of NMR resonances, where necessary, were facilitated by NOE, ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$-COSY, and HETCOR experiments. The trans/cis amide assignments were based upon observations of an NOE effect on either the characteristic bridgehead $\mathrm{H}_{1}$ hydrogen or alternatively at the $\mathrm{H}_{3}$ methylene hydrogen signals upon irradiation of the major or minor acetyl methyl singlets; italics denote minor rotamer peaks. Amide trans/cis ratios were obtained by integration of nonoverlapping ${ }^{1} \mathrm{H}$ or ${ }^{19} \mathrm{~F}$ NMR peaks. Throughout this paper, we have chosen to use syn/anti nomenclature to identify the stereochemistry of substituents on the non-nitrogen containing bridges. This is to avoid the use of exo/endo nomenclature, confusing to those accustomed to naming related all-carbon-bridged bicyclic structures. The bridge with the nitrogen heteroatom is always the main bridge of highest priority. Thus, all substituents anti to nitrogen are endo.
